A map of the Eastern United States, showing major cities and highways. Overlaid on the map are numerous orange circles of varying sizes, representing biodiversity data points. The circles are concentrated in the central and eastern parts of the region, particularly around the Ohio River valley and the Appalachian area. A semi-transparent white box is overlaid on the map, containing the title text.

# A Quick Intro To Biodiversity Data and Modeling

ESMC Webinar, April 28, 2026

# ASU Center for Biodiversity Outcomes

- Bring biodiversity to the center of the world's decision making
  - Many ongoing NGO partnerships
- Transform biodiversity conservation investments and decision-making

**Leah Gerber**  
CBO Director

**Shirley-Ann Behravesh**  
Corporate Engagement Lead

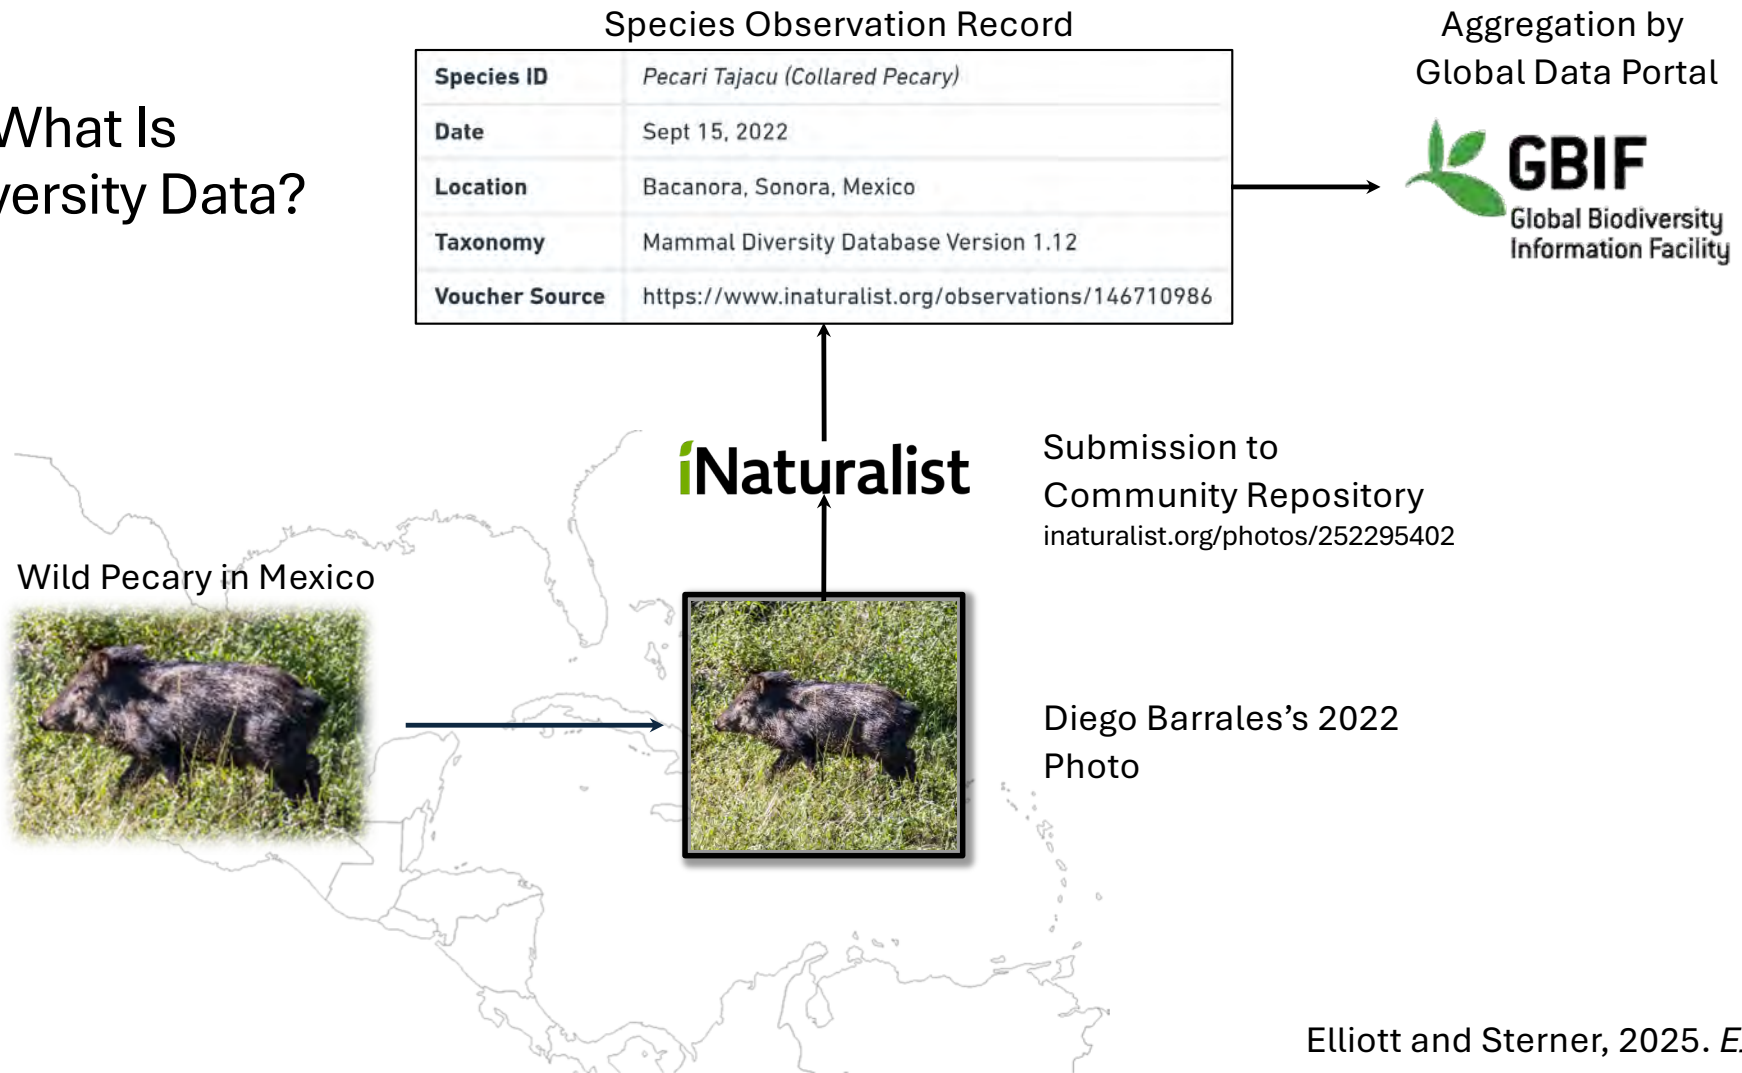

<https://globalfutures.asu.edu/center-for-biodiversity-outcomes/>

# Motivating Questions for ESMC

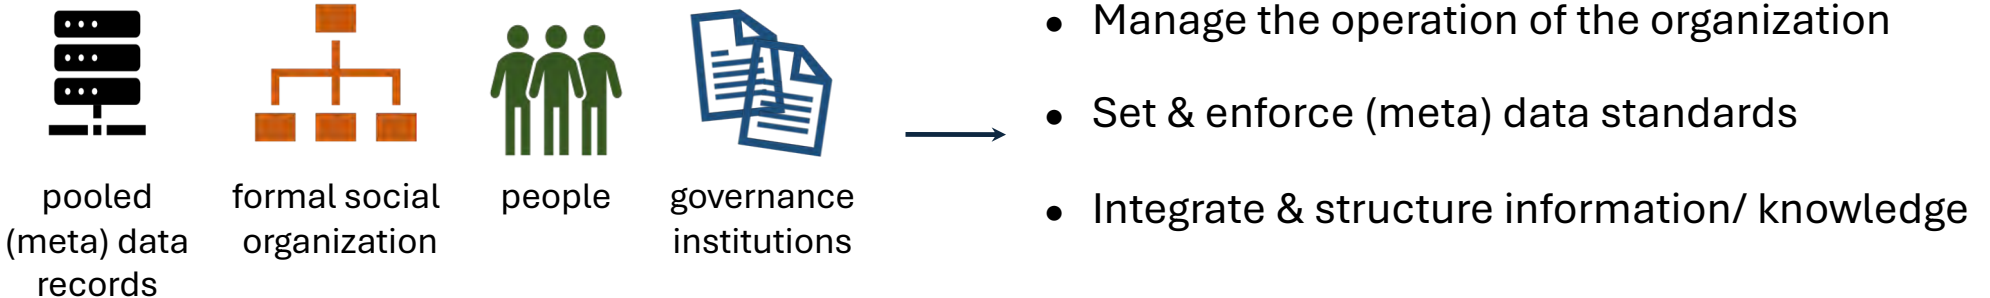

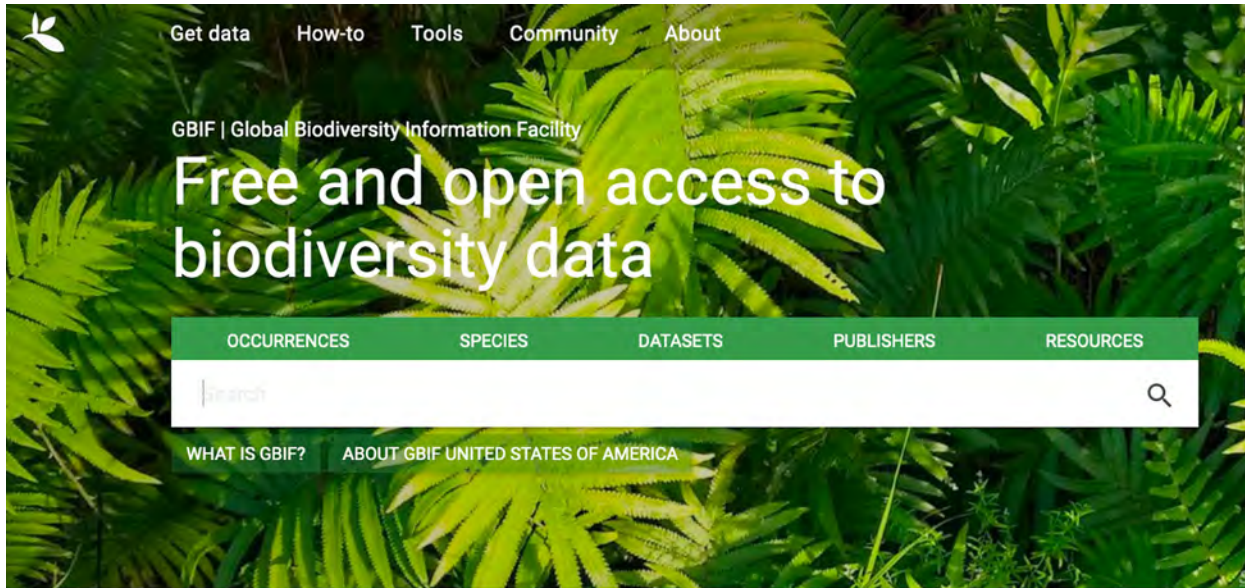

- What are the benefits of alternative farming practices for biodiversity?
- How can these benefits to biodiversity create benefits to farmers?

In this webinar, I'll go into more depth on where data about biodiversity comes from and how it can be used in predictive models

# What Is Biodiversity Data?

# Data Repositories: More than Websites

# Example: SEINet Symbiota Portal

A database of 24 million digitized herbarium specimen collections curated primarily by botanists.

Includes map search functions

A screenshot of the SEINet Arizona - New Mexico Chapter website. The header features the SEINet logo and the text "Arizona - New Mexico Chapter" against a background of a desert landscape. A navigation menu includes links for Home, Specimen Search, Images, Flora Projects, Agency Floras, Dynamic Floras, Additional Websites, Resources, and Data. A "Sign In" button is in the top right. Below the header is a "Taxon Search" input field with a "Search" button. The main content area has a "Welcome to SEINet" heading, followed by a paragraph describing the database and its partners. A "Plant of the Day" section features a photograph of a pine tree and a link to a quiz: "What is this plant? Click here to test your knowledge".

## Welcome to SEINet

The Arizona - New Mexico Chapter of SEINet started as a gateway to distribute botanical data of interest to the environmental research community within Arizona and New Mexico. Over time this database grew to include many collections across North America. When you search this portal, or any of the other SEINet portal partners, you are getting results from our one central database. The SEINet portal network contains 24 million records from 456 collections. Collections are organized into regional consortia that are accessed through different websites but share a central database. Some examples include: the [Consortium of Midwest Herbaria](#), [Consortium of Southern Rocky Mountain Herbaria](#), [Intermountain Regional Herbarium Network](#), [Madrean Discovery Expeditions \(MDE\)](#), [Mid-Atlantic Herbaria Consortium](#), [North American Network of Small Herbaria](#), [North Great Plains Herbaria](#), [Red de Herbarios Mexicanos](#), [SERNEC \(Southeast USA\)](#), and the [Texas Oklahoma Regional Consortium of Herbaria \(TORCH\)](#).

Here you'll find taxon pages, checklists, and other tools to help you understand the plants in your region of interest.

Join SEINet as a regular visitor and please send your feedback to the [Support Hub HelpDesk \(help@symbiota.org\)](#). Visit the [Data Usage Policy](#) page for information on how to cite data obtained from this web resource.

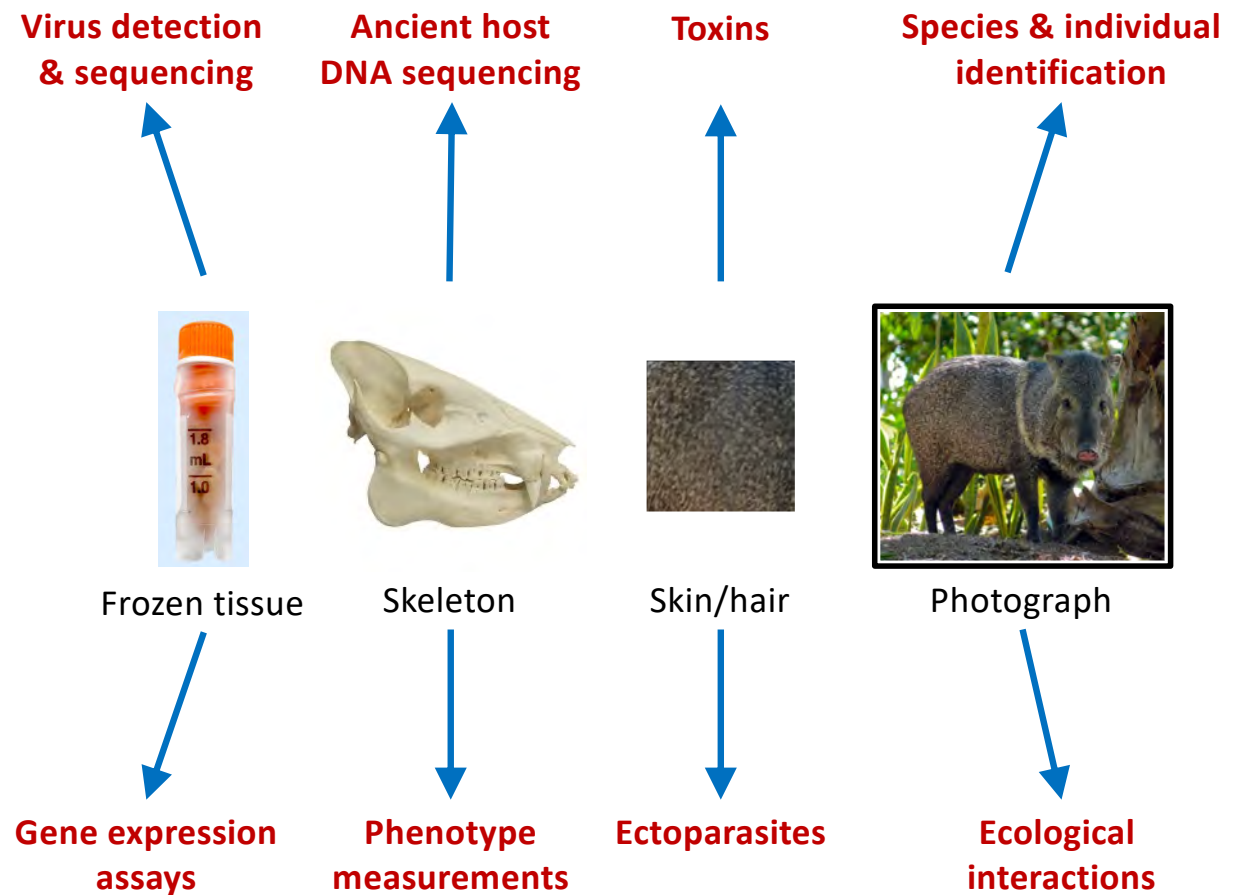

### Plant of the Day

What is this plant?  
[Click here to test your knowledge](#)

# Importance of Vouchers for Biology

Physical and digital vouchers are useful for all sorts of research in biology

Vouchers are stored in research collections for long-term reuse by different projects

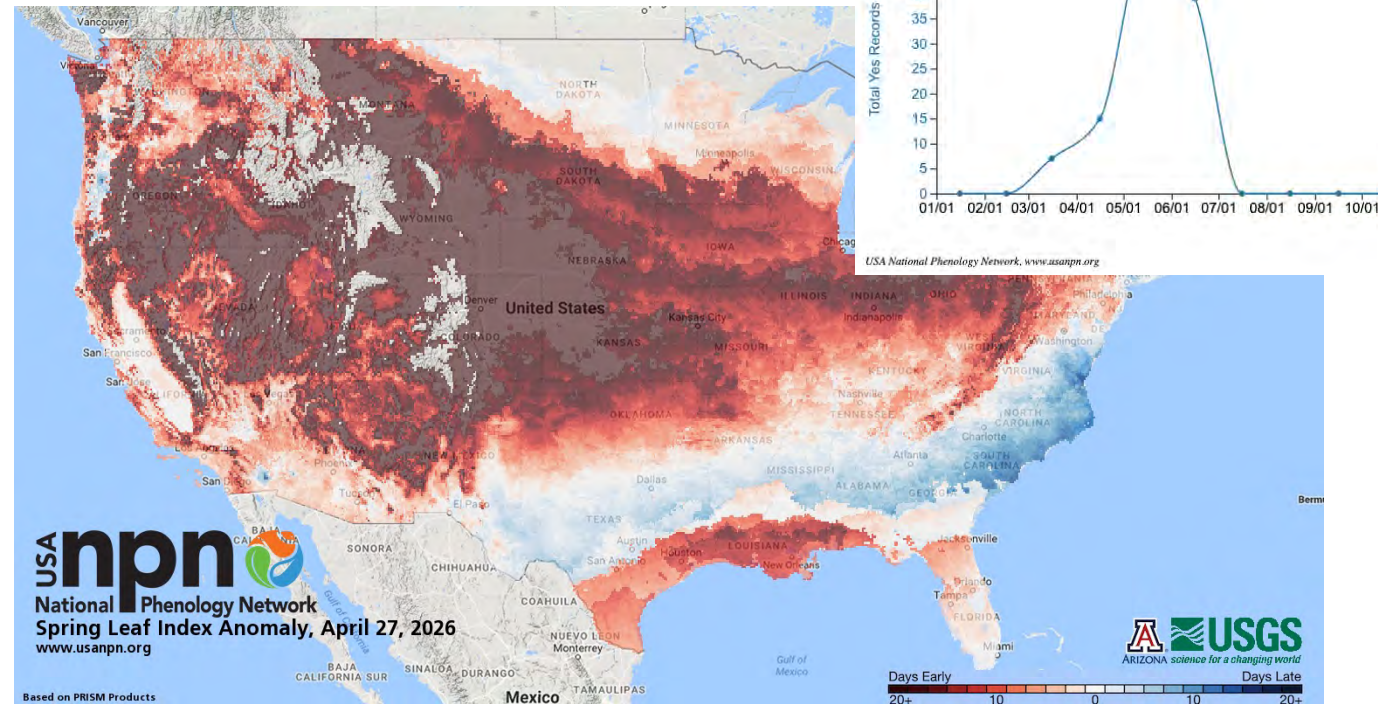

# Example: National Phenology Network

Phenology is the seasonal timing of biological events, such as leafing, flowering or insect emergence

Many species are sensitive to climatic factors such as temperature, rainfall, and sunlight

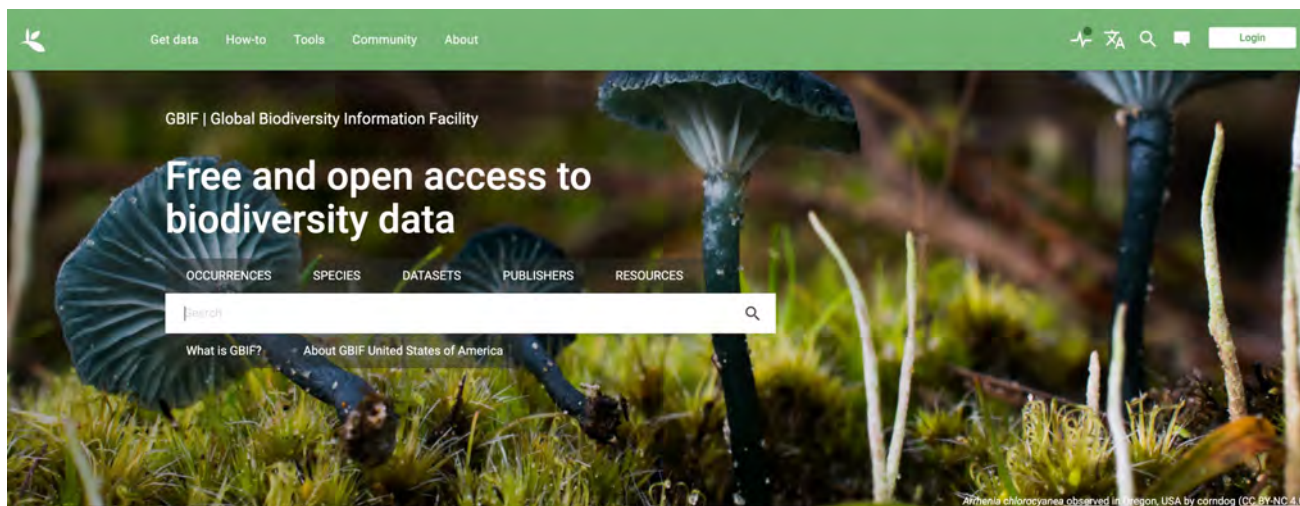

Shifting timelines can disrupt symbiotic relations such as flowering and pollination

<https://www.usanpn.org/>

# Global Biodiversity Information Facility (GBIF)

What are the geographic distributions of all species?

3,681,799,377  
Occurrence records

121,894  
Datasets

2,682  
Publishing institutions

14,578  
Peer-reviewed papers  
using data

# Taxonomic Bias in GBIF Database

All: **3.7B** occurrences

Source: [gbif.org](http://gbif.org)

Birds (Aves): **2.2B** occurrences

Mammals (Mammalia): **41M** occurrences

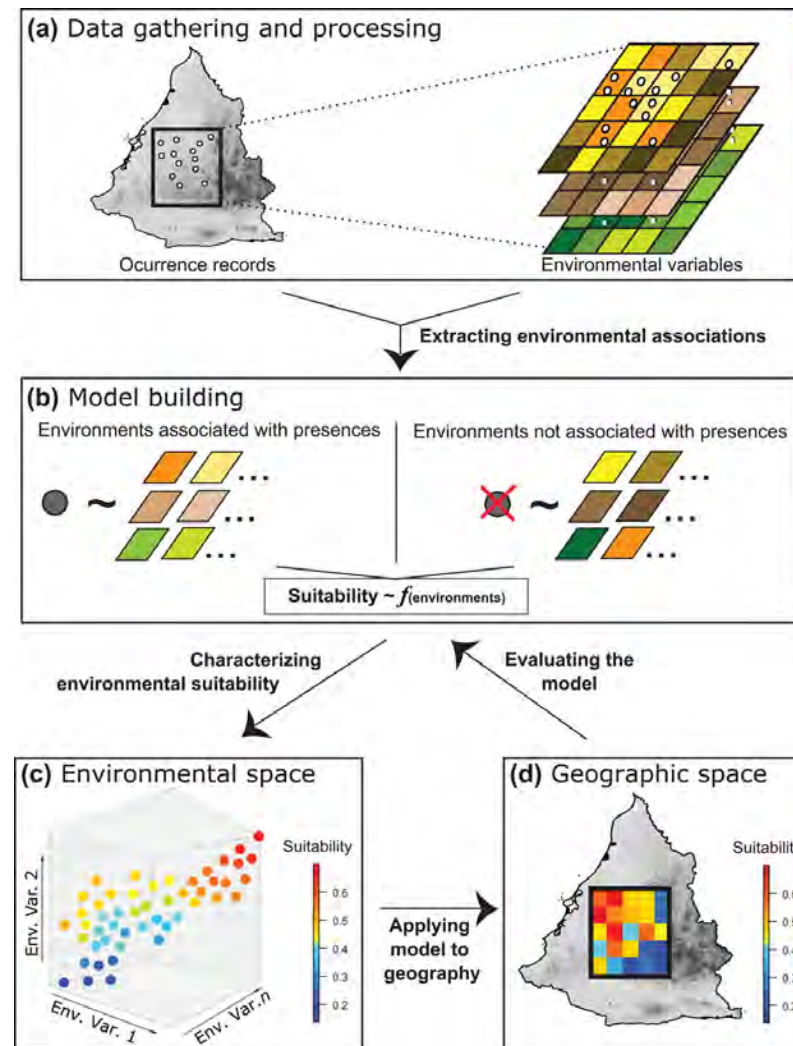

# Species Distribution Models

Also called “Ecological Niche Models”

In short: can I infer where a species might be based on observing its presence or absence at particular places?

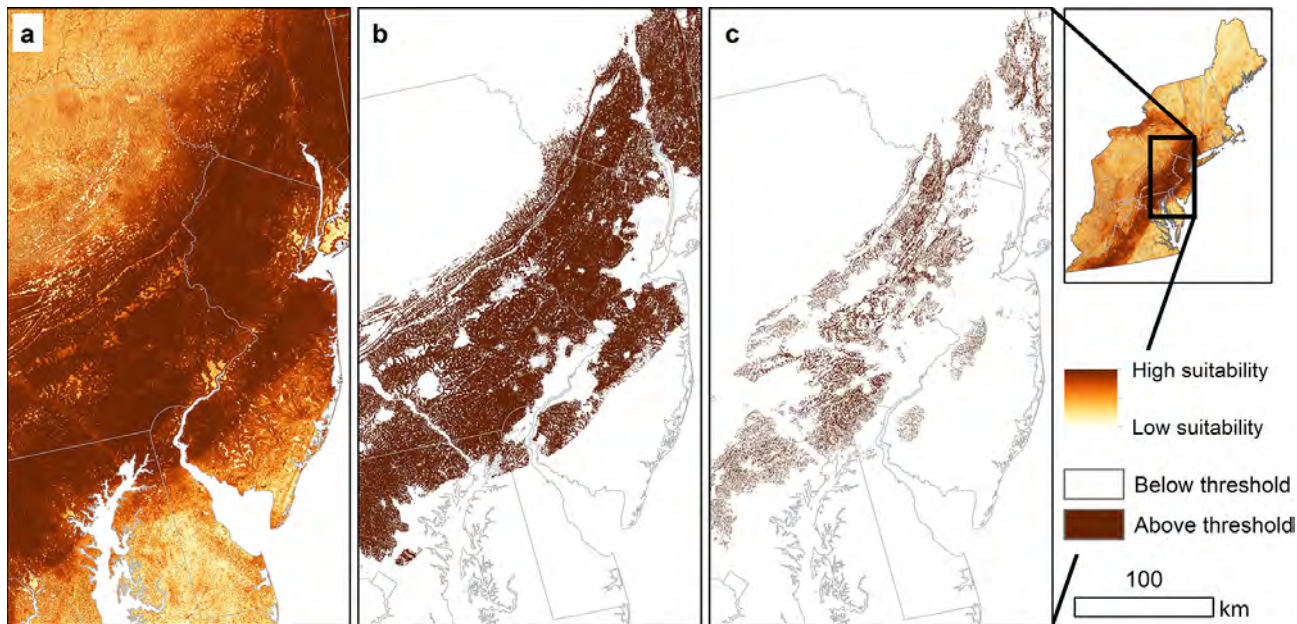

Models use machine learning methods to correlate species observations with other variables such as climate, geography, other species, etc.

Soley-Guardia et al. 2024; <https://doi.org/10.1111/ecog.06852>

# Example Habitat Model for Threatened Bog Turtle Species

Where is the most likely habitat for Bog Turtles (*Glyptemys muhlenbergii*)?  
Full model (a) with low versus high thresholds (b and c) for habitat

**But** highly sensitive to  
quality of input data:  
garbage correlations  
in -> garbage  
correlations out

Sofaer et al. 2019; <https://doi.org/10.1093/biosci/biz045>

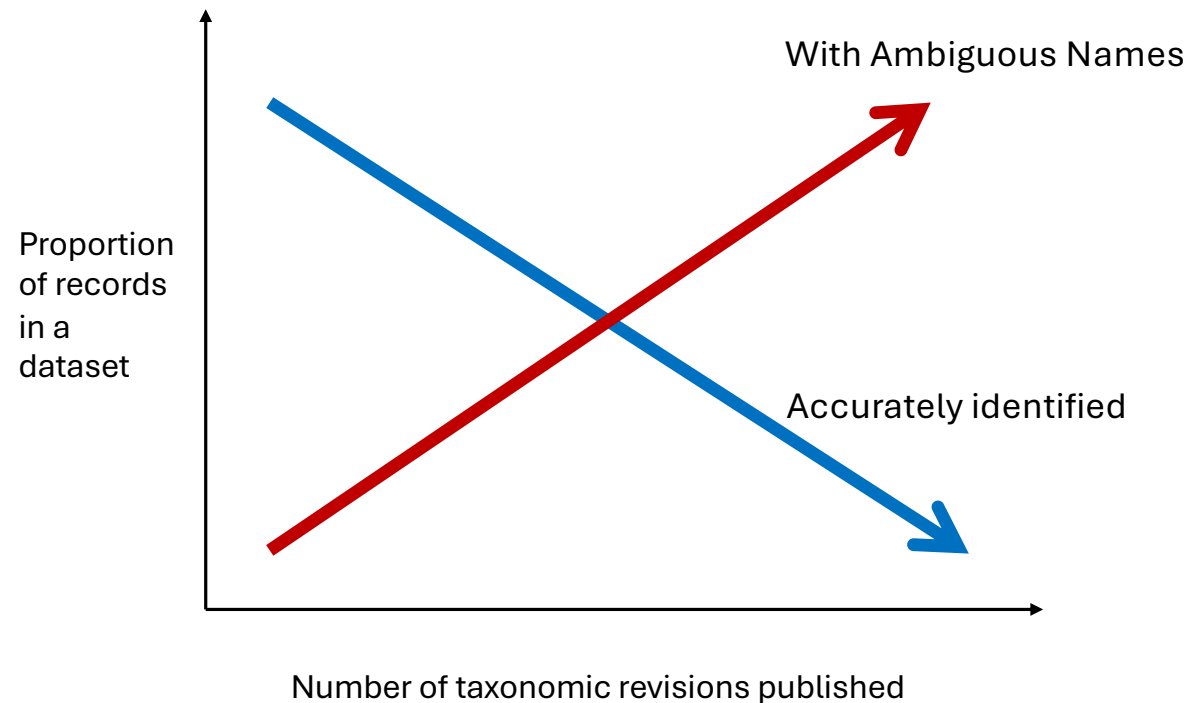

# Long-Term Data Needs Long-Term Care

Every observation is labeled with metadata categories, especially a taxonomic name for the observed species

As categories get revised with time, datasets need their metadata labels updated

Otherwise names for categories tend to become increasingly ambiguous and incorrect

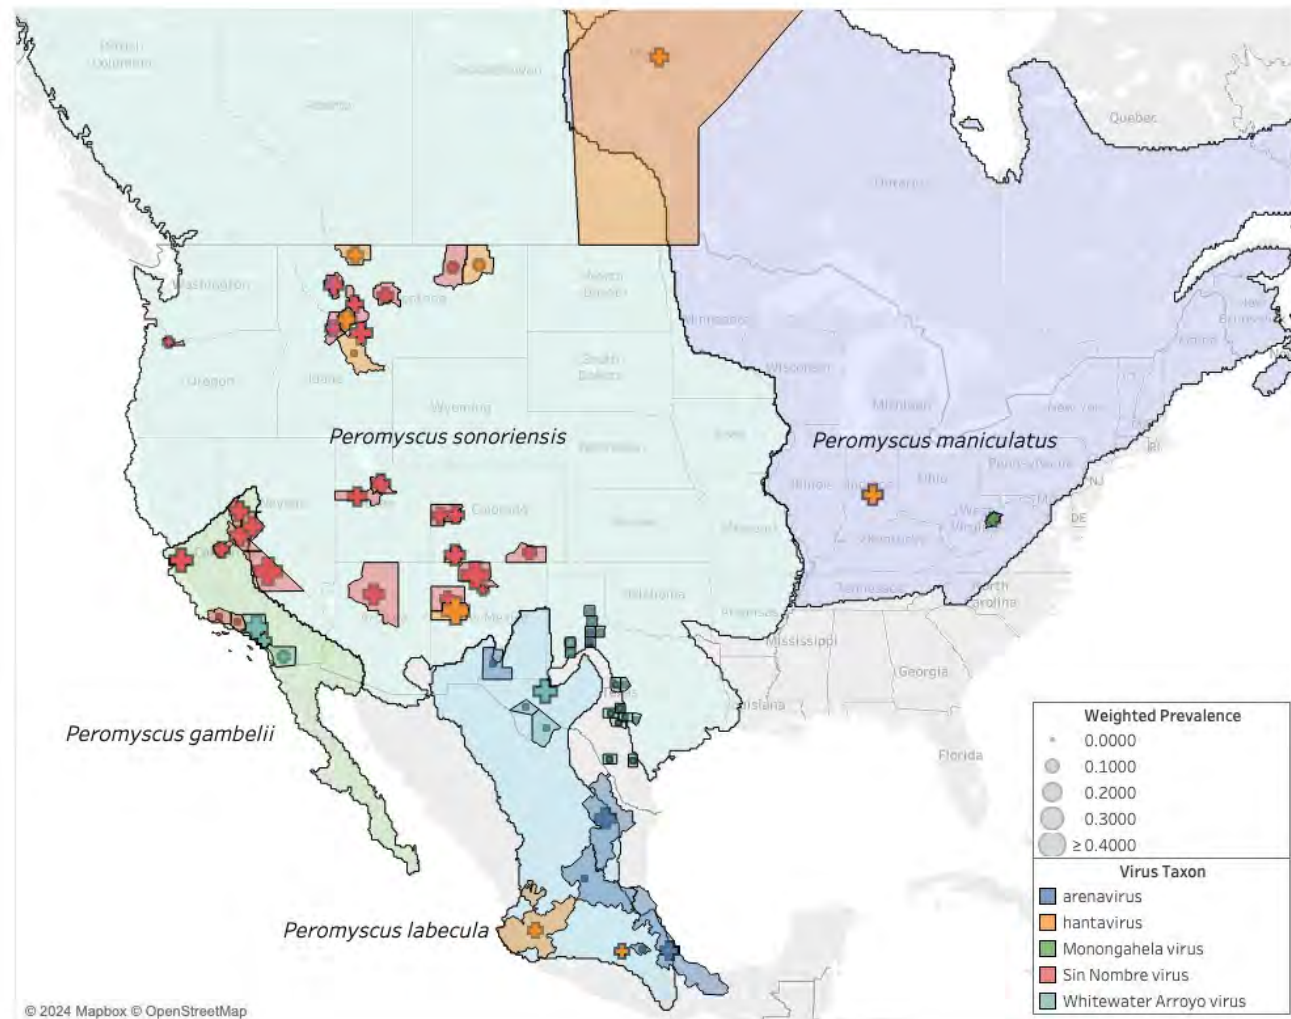

## Taxonomic accuracy and ambiguity of biodiversity data records over time

## Ecology Example: Rodent Reservoirs Of Hantaviruses

The North American  
deer mouse *Peromyscus  
maniculatus* was recently  
split into 4 species

These changes can strongly  
affect biological  
conclusions, e.g. about  
which host species maintain  
zoonotic pathogens

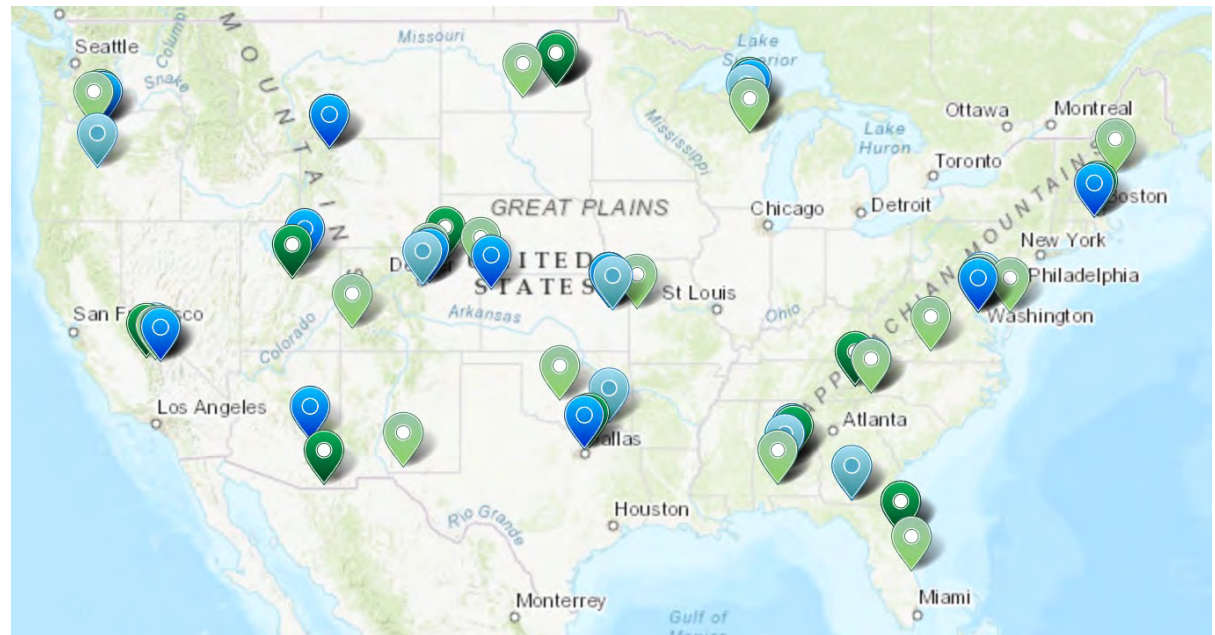

Finkbeiner et al., 2025. *PLoS Pathogens*.

# NEON Biorepository

**National Ecological Observatory Network (NEON)** is NSF's largest investment in long-term biological research infrastructure (~\$500M annually)

NSF selected ASU as primary repository for >100k material samples annually from >80 sites across nation

Map of NEON Sampling Sites in 48 States

# Iterative Forecasting in Ecology

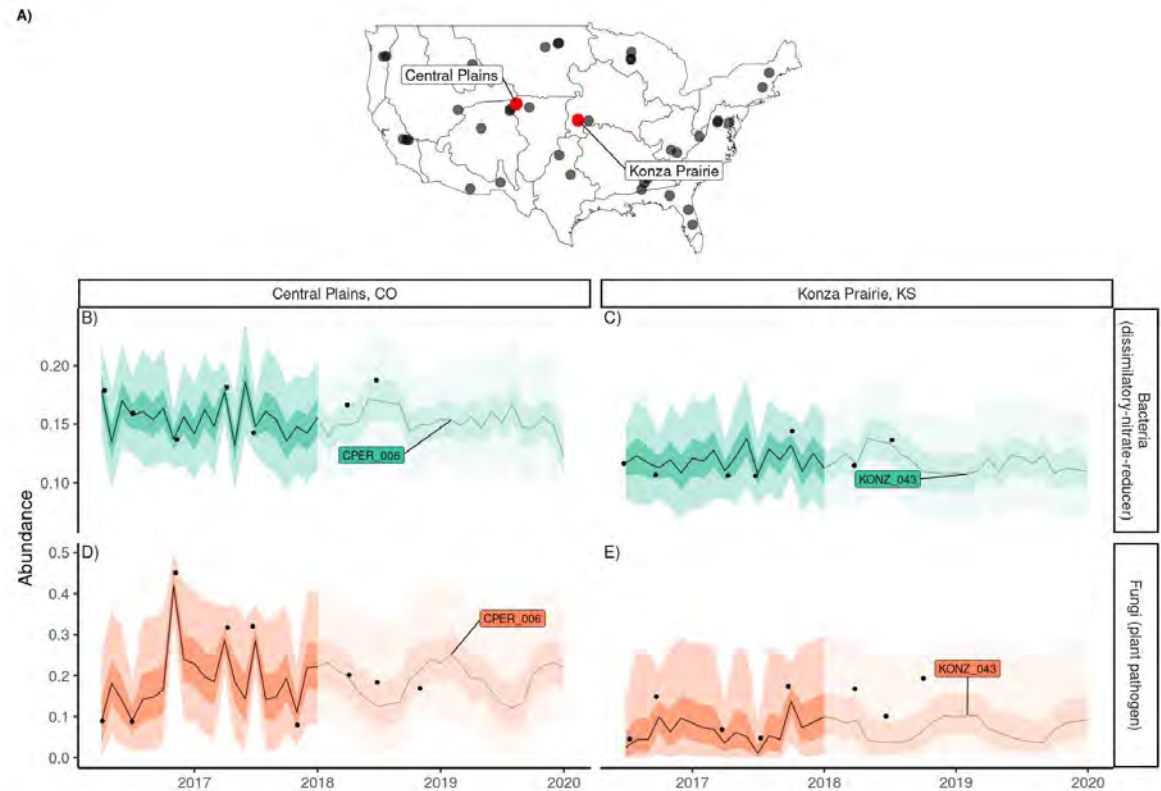

A major shift from site-based, explanatory regression models

Uses iterative updating of model set based on predictive outcomes

# Using NEON to Forecast Microbiota

Werbin et al. used soil genomic and environmental surveys from NEON sites to develop the first forecasts of soil microorganisms across biomes and time.

“We find that the abundance of fungi and bacteria can be predicted with 50% and 91% accuracy, respectively, for up to a year ahead of time, by simulating seasonal cycles in taxon abundances.”

# Conclusion

- Biodiversity data are usually curated by communities before they reach aggregators such as GBIF
- The data enables powerful spatial and temporal models, but take substantial validation and cleaning for high-stakes decisions
- There are many more types of data and models than I covered here!

# Acknowledgements

Thanks to you all for coming and listening today!

# Biodiversity Estimation for Agriculture Tool (BEAT)

A Framework to Quantify Biodiversity  
Outcomes in Agricultural Systems

# Overview

## Quantifying Biodiversity

Biodiversity is essential to resilient agricultural systems but it's long been one of the most difficult outcomes to measure, verify, and scale.

To help address this challenge, we're proud to introduce the **Biodiversity Estimation for Agriculture Tool (BEAT)** - a new component of ESMC's EcoHarvest MRV platform.

Separating Biological Response, Realized Impact, and Restoration Opportunity

# Core Functionality

## Habitat Size

Measures the extent of land under biodiversity management.

## Habitat Quality

Measures the health and sustainability of habitats.

## Time Response

Assesses how quickly ecosystems can adapt and recover.

## Weighted Functional Presence

Assesses species presence and their ecological roles.

## Comprehensive Assessment

Evaluates multiple biodiversity factors for informed decision-making.

## Conservation Priority

Identifies critical areas needing protection and support.

# Model Design and Practical Strengths

- Purpose-built, not overly complex: Designed to capture core drivers of outcomes, not every micro-detail
- Handles real-world data variability: Highly complex models can become sensitive to small nuances, making results harder to compare across fields and regions
- Ensures consistency and comparability: Simplified structure allows for stable, repeatable outputs across diverse datasets
- Captures what matters most: Focuses on key signals (BMP impact, baseline conditions, scale) rather than noise
- Market-ready outputs: Produces results that are interpretable, scalable, and usable for crediting and reporting

# Key Assumptions

- BMP effects are consistent under similar soil, climate, and management conditions
- Baseline is representative of typical system state
- Variability averages out at larger spatial scales
- Model is robust to small input differences
- Focus on primary drivers (BMP, baseline, scale), minimizing noise

# Retrospective Analyses

# 2024 Dataset Overview

- Total fields: 1,169
- States represented: 11
- States with  $\geq 5$  fields (used for stats): 9 states
- KS, NY, MN, VA, PA, NE, ND, MD, CO

Total acreage analyzed: ~85,500 acres across 1,169 fields

Statistical analysis coverage: ~85,300 acres ( $\geq 5$  field states)

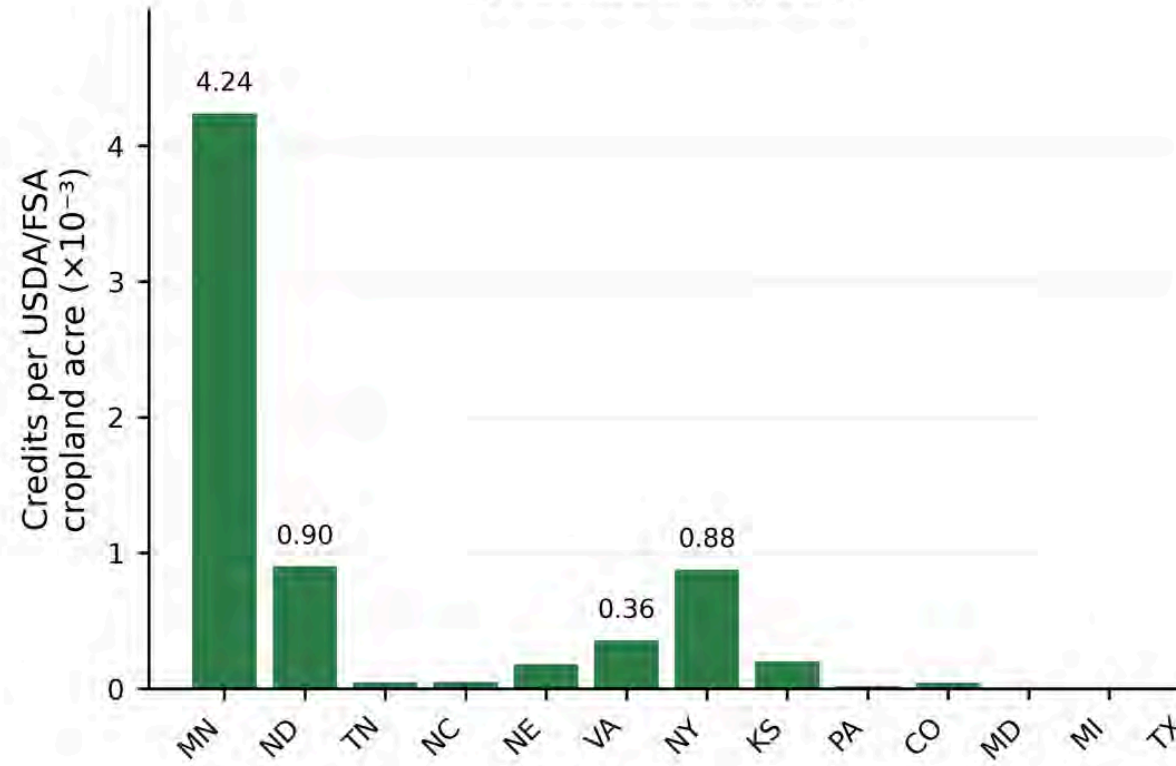

# 2024

**A. BMP Efficiency (Biological Response)**

Bars show mean ± SE. Letters: Games-Howell, α = 0.05.

**B. Credits per USDA/FSA Acre (Realized Impact)**

Derived scale metric; no statistical test.

**C. Restoration Potential (Opportunity)**

Bars show mean ± SE. Letters: Games-Howell, α = 0.05.

North Dakota → highest biological response  
 Minnesota → highest impact + opportunity  
 Tennessee → high response, low impact

- Scope: Multi-state dataset across all 2025 projects
- Fields: 916 total fields | AGIM\_2025: 88 clean fields (from 123)
- Geography: 10+ states ( $\geq 5$  fields used for statistical testing)
- Total acreage analyzed: ~54,850 acres
- Dataset reflects full portfolio with AGIM quality-filtered

### **Statistical approach:**

Welch ANOVA + Games–Howell post hoc  
Significance letters on charts  
Bootstrap error bars for key metrics

### **Data quality:**

AGIM fields filtered to high-confidence subset  
Final dataset reflects robust, production-ready analysis

# 2025 Dataset Overview

## 2025

**A. BMP Efficiency  
(Biological Response)**

Bars show mean  $\pm$  SE. Letters: Games-Howell,  $\alpha = 0.05$ .

**B. Credits per USDA/FSA Acre  
(Realized Impact)**

Derived scale metric; no statistical test.

**C. Restoration Potential  
(Opportunity)**

Bars show mean  $\pm$  SE. Letters: Games-Howell,  $\alpha = 0.05$ .

North Carolina  $\rightarrow$  highest response + opportunity  
 Virginia  $\rightarrow$  highest realized impact  
 Strong divergence between panels

# BEAT Validation

- ✓ Captures spatial ecological variation
- ✓ Separates:
  - Biological response
  - Implementation scale
  - Future opportunity
- ✓ Matches ecological theory:
  - Landscape dependence
  - Context-specific response
  - Non-linear ecosystem services

Scaling is not aligned with impact.

High-efficiency states like Tennessee (~20+ BU/ac), North Dakota (~7 BU/ac), and Minnesota (~5 BU/ac) show the strongest per-acre outcomes but have limited acreage.

Meanwhile, Kansas (~0.05 BU/ac) and Colorado (~0.01 BU/ac) dominate scale despite very low efficiency—leading to suboptimal total credit generation.

**BEAT transforms biodiversity accounting from**

**“how many acres” →**

**“how ecosystems respond, perform, and can improve.”**
